Campylobacter control in meat

Contents

Objective

To create a technology landscape report on ***Campylobacter*** **control in meat**

- Identify market players with prolific IP activity in the technology area
- Segment the players by the industry they belong to

Note: *This report is just a template and gives an indication of what the paid report contains.*

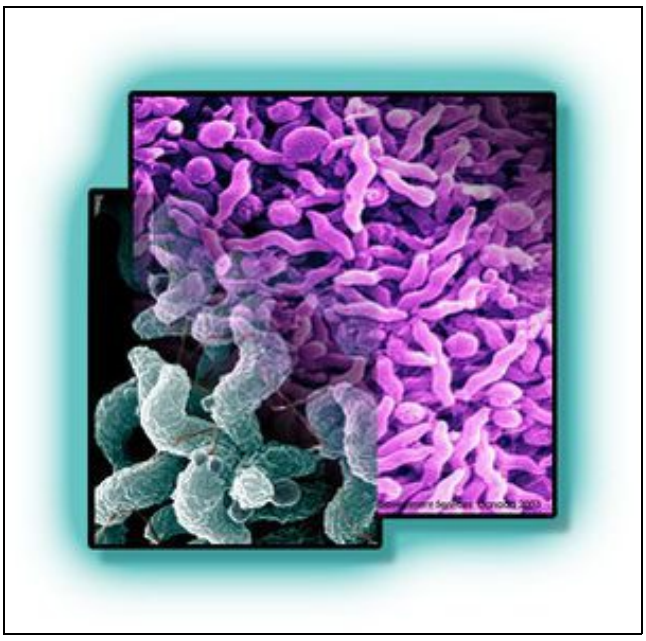
Background

Campylobacter bacteria are a major cause of foodborne diarrhoeal illness (Campylobacteriosis) in humans and are the most common bacteria that cause gastroenteritis worldwide. *Campylobacter* infections are generally mild, but can be fatal among very young children, elderly and immune-suppressed individuals [WHO] The *Campylobacter* spp. associated with gastrointestinal illness in humans include *C. jejuni, C. coli, C. lari, C. fetus* and *C. upsaliensis* [Food safety and Authority of Ireland]



Campylobacter **spp.**
The bacteria normally inhabit the intestinal tract of warm-blooded animals such as poultry, cattle, pigs, sheep, ostriches and shellfish; and in pets, including cats and dogs. Hence they are frequently detected in foods derived from these animals. Most often, carcasses or meat are contaminated by *Campylobacter* from faeces during slaughtering. The main route of transmission is generally believed to be foodborne, via undercooked meat and meat products, as well as raw or contaminated milk. Contaminated water or ice is also a source of infection [WHO] Poultry meat is known to be one of the most important sources of *Campylobacter* for humans. However, *Campylobacter* colonization in the gut is prevalent in all animals. *Campylobacter* is mainly a contamination of the surface of the carcass and bovine, ovine and porcine carcasses and can also test positive for *Campylobacter* immediately after slaughter. Storage (cooling down) of the carcasses under dry air conditions results in the death of *Campylobacter* and reduced *Campylobacter* counts after a prolonged time. At retail level, the *Campylobacter* contamination levels of non-poultry meat are clearly less than the levels in poultry. It is to be expected that red meat contributes to human campylobacteriosis to a much lesser degree than poultry [Wagenaar et al.]

The *Campylobacter* spp. are sensitive to freezing, heating (pasteurisation/cooking), drying, acidic conditions (pickling), disinfectants and irradiation. They survive poorly at room temperature (21°C) and in general survive better at cooling temperatures. They can grow on moist foods at temperatures between 37°C and 45°C, with an optimum temperature of 42°C. It has been estimated that consumption of a small number of organisms (500 or less) may be associated with illness. Therefore, the fact that the organism does not multiply very effectively in most foods does not prevent it from causing foodborne illness. The organisms normally die quickly in the presence of air and are very sensitive to oxygen breakdown products. Vacuum or gas packaging appears to have little effect on their survival [Food safety and Authority of Ireland]

Strategies aimed at reducing *Campylobacter* counts on carcasses and raw chicken meat products include

- Improved hygiene during processing
- Freezing of carcasses at processing plants
- Irradiation
- Chemical decontamination of carcasses by chlorine or trisodium phosphate
- Marination of the raw fresh chicken meat
- Spreading of a mixture of dry seasoning compounds on the surface of chicken meat products, etc. [González and Hänninen]

Concept table

Relevant Patents

S. No	Patent/ Publication no.	Assignee/ Applicant	Year	Title	Focus	Dolcera Summary
1	US7767240B2	Albemarle Corporation	2010	Microbiological control in poultry processing	Microbiological control	The present invention deals with the preparation of halogen-based antimicrobial derivatives which are highly efficient, cost effective and can be widely used in the poultry processing industry. The microbicidal compound can be applied directly to the poultry carcass, or to the equipments, instruments, apparatus, chiller tanks, etc. used during the processing and is effective against *Campylobacter jejuni*, *Campylobacter coli*, *Campylobacter lari*, etc.
2	US20090239912A1	University of Arkansas	2009	Concentrated, non-foaming solution of quaternary ammonium compounds and methods of use	Microbiological control	A major challenge in the meat processing industry is to deliver a pathogen-free product to the consumers. The present invention deals with the preparation of compositions containing quaternary ammonium compounds (QAC) which prove effective against a broad spectrum of microorganisms including *Campylobacter* attached to the surface of meat products. The surface adhering microbes are killed, inactivated or their growth is retarded, making the meat products safe for consumption.
3	US5494660A	Emory University	1996	Method for inhibiting microbial binding to surfaces	Reducing adhesion of microorganisms to surfaces	The present invention deals with the preparation of a biologically active copolymer which is effective in reducing the adhesion of pathogenic microorganisms on the surface. The compound is either given in the form of feed to the poultry birds to reduce the gut population of pathogenic bacteria or applied to the surface of skin or meat

						from the poultry animals. It is effective against a number of food-borne pathogens including *Salmonella, Campylobacter*, etc.
